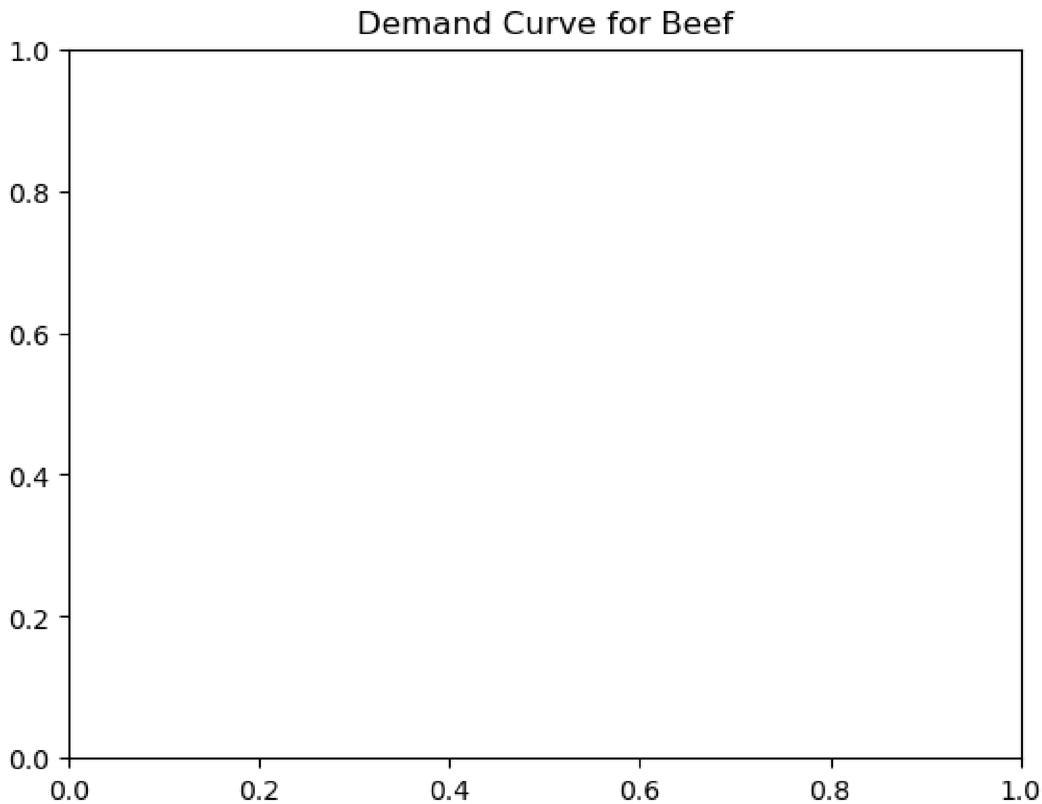
Question 1: Create a scatterplot with a best-fit line (using `fit_line = True`) across the points. Trendlines are helpful because they consolidate all the datapoints into a single line, helping us better understand the relationship between the two variables.

In [5]:
```
...
plt.title("Demand Curve for Beef");
```



Question 4.2: Assign the number (i.e `1`, `2`, `3`, or `4`) to `slope_only` that best represents the interpretation of the slope term of the demand curve in question `4.1`.

1. A 1 cent increase in the price per pound of beef is associated with a 0.244% increase in the quantity demanded per quarter.
2. A 1 cent decrease in the price per pound of beef is associated with a 0.244% decrease in the quantity demanded per quarter.
3. A 1 cent increase in the price per pound of beef is associated with a 0.244% decrease in the quantity demanded per quarter.
4. A 1 cent increase in the price per pound of beef is associated with a 0.244% increase in the quantity demanded per quarter.

```
In [ ]: slope_only = ...
```

```
In [ ]: grader.check("q4_2")
```

Question 5.2: Let's say that Matt wants to find the what a 15% increase in the price of beef is associated with in terms of a percentage change in the quantity demanded per quarter. Use `log_log_demand_params` to find the exact result and assign the result to `q5_2`.

```
In [ ]: q5_2 = ...
```

```
In [ ]: grader.check("q5_2")
```

Question 5.4: Explain your answer from question `5.3`. There is no correct answer here; any answer with valid justification will be awarded credit.

Type your answer here, replacing this text.

Question 6: Which demand curve do you think is the most appropriate to model the demand of beef? There is no correct answer here; any answer with valid justification will be awarded credit.

Type your answer here, replacing this text.
